## Evaluation of chest computed tomography features in COVID-19: a single-center retrospective study

Akshat Sanjay Shukla<sup>1\*</sup>, Sanjay Rajendraprasad Shukla<sup>1</sup>, Feral Ravi Daruwala<sup>1</sup>

### Abstract

**Background:** Even though Real-Time Polymerase Chain Reaction (RT-PCR) is a gold standard for confirming COVID-19, it continues to be plagued by a lack of RT-PCR kits and the potential of false-negative results. Hence, during the second wave of COVID-19 in India, Computed Tomography (CT) scan is an emerging diagnostic tool in evaluating the severity of illness in COVID-19 pneumonia. The present study endeavored to assess chest CT features of COVID-19 pneumonia in Indian population.

**Methods:** This was a single-center, retrospective, observational study conducted in 300 consecutive adults RT-PCR confirmed COVID-19 patients from 1, Jan 2021 to 31, March 2021 at a private radio diagnostic center. Data regarding baseline demographics, clinical and laboratory characteristics, extent, pattern, and type of abnormal CT findings were noted.

**Results:** The study population (204 males and 108 females) had mean age of  $43.18 \pm 8.27$  years. Our study's most common clinical presentation was cough (48.1%) and fever (47.1%), respectively. Lung parenchymal abnormalities were found in 294 (94.2%) patients. Abnormal CT findings revealed the involvement of bilateral (45.6%) and multilobar (42.9%) with a predominant peripheral (92.3%) and posterior (80.8%) distribution. According to the type of opacity, Ground Glass Opacity (GGO) was the dominant abnormality found in 270 (91.8%) patients, in which pure GGO (36.7%), GGO with crazy paving pattern (39.8%), and GGO mixed with consolidation (52.0 %) were noted. Perilesional or intralesional segmental or subsegmental pulmonary vessel enlargement was found in 192 (65.3 %) patients.

**Conclusion:** During the second wave of COVID-19, a chest CT scan is a modality of choice in diagnosing COVID-19 pneumonia and related lung parenchymal changes.

**Keywords:** COVID-19, Computed Tomography, Lung Disease, Reverse Transcriptase Polymerase Chain Reaction, SARS-Cov-2, India

### Background

In late December 2019, a novel enveloped single-stranded RNA virus, known as Severe Acute Respiratory Syndrome CoronaVirus 2 (SARS-CoV-2), caused a highly infectious disease called CoronaVirus Disease (COVID-19) in Wuhan City, Hubei province, China [1]. The second wave of COVID-19 continues to increase its effect worldwide [2] and more so in India. The COVID-19 has been diagnosed in more than 156 million patients worldwide, and more than 3 million infected people have died, whereas, especially in India, more than 21 million confirmed patients with more than 2 lakh deaths have been reported [3]. Clinical presentation of COVID-19 modifies from asymptomatic through symptomatic to critically ill

patients [4, 5]. Timely and accurate detection of COVID-19 patients are essential to seclude afflicted patients from not infected individuals and restrain its spread. Real-Time Reverse Transcription Polymerase Chain Reaction (RT-PCR) is a standard laboratory technique used for the diagnosis of COVID-19 infection; nevertheless, the sensitivity of this technique varies from 42-71% due to its associated limitations, as such, suboptimal sampling technique, low viral load in the nasopharyngeal region, or impediments in assay performance [6-9]. Importantly, in the second wave of COVID-19, the number of false-negative RT-PCR results has increased dramatically due to a virus mutation; the virus in the current wave of infection has a shorter incubation period and a higher tendency to involve the lungs rather than the upper respiratory tract during incubation period [10, 11]. However, recent studies have revealed the significance of chest Computed Tomography

A full list of author information is available at the end of the article

(CT) in the detection and diagnosis of COVID-19; chest CT is an excellent diagnostic tool to confirm the lung pathology in suspected COVID-19 patients due to its higher sensitivity (97%) as opposed to RT-PCR [12-14]. Interestingly, chest CT features of COVID-19 are closely similar to other viral pneumonia, which consist of the following features: Ground Glass Opacities (GGO), crazy paving pattern, and consolidations with peripheral and basal predominance. These chest CT features are observed in peak stage [9-13] days after the onset of COVID-19 infection) [13, 14]. Even though India has been reporting a spike in COVID-19 cases, there is a scarcity of studies describing the chest CT findings in COVID-19 patients in India [15, 16]. Hence, uncertainty thrives concerning the chest CT features of COVID-19 in India. Given this context, we sought to investigate the chest CT features of COVID-19 pneumonia in the Indian population.

## Methods

### Study population

A single-center retrospective, observational study was conducted in 312 consecutive adult COVID-19 patients from 1 January 2021 to 31 March 2021 at Shukla Diagnostic Center, Balaghat, Madhya Pradesh, India.

### Inclusion and exclusion

Irrespective of gender and availability of RT-PCR report, patients (more than 18 years of age) with typical symptoms of COVID-19 such as fever, cough, fatigue, sore throat, and dyspnea were included. All the patients referred to our private radio diagnostic center were subjected to high-resolution computed tomography (HRCT) chest. Malignancy, immunodeficiency, pregnancy, and absence of all medical records were the exclusion criteria.

### Sample size

A sample size calculation was computed using Raosoft software. ([http://www.raosoft.com/sample\\_size.html?nosurvey](http://www.raosoft.com/sample_size.html?nosurvey)) on the assumption of a prevalence of disease of 50%, and marginal error of 5.62% with a population of 20,000 and confidence interval of 95%. The minimum sample size required would be at least 300.

### Clinical and laboratory data collection

The following data were recorded using a predefined proforma; a) baseline demographics, b) clinical and laboratory characteristics and c) extent, pattern, and type of abnormal CT findings. RT-PCR was performed on nasopharyngeal swabs or aspiration, using RealStar® SARS-CoV-2 RT-PCR Kit (Altona Diagnostics) or Cobas® SARS-CoV-2 Test (Roche).

### Chest CT protocols

Patients were subjected to chest CT after collection of a nasopharyngeal swab. Chest CT was done on an average of 5.8 days (range 3–9 days) after symptom onset. All the chest CT scans were acquired on a 32 slice multi-detector CT unit (Siemens Somatom Go Now) without contrast medium injection. The scanning parameters were as follows: tube voltage of 110kVp, tube current of 90-130 mAs, and collimation of 16 × 0.6, and a beam pitch of 1.5. The CT images were obtained in a single inspiratory breath-hold. Using a high-

frequency reconstruction algorithm, images were reconstructed using a reconstruction increment of 0.7-1 mm thick slices. All the images were viewed at lung (window width: 1200–1500 HU; window center: 500-600HU) and mediastinal (window width: 300–400HU; window center: 40 HU) window settings. Decontamination of the CT suite was done using surface disinfectants (70% ethanol or 0.1% sodium hypochlorite).

### Image interpretation

All CT images presented in the current study belong to our center (Shukla Diagnostic Center, Balaghat, Madhya Pradesh, India). CT images were analyzed on an Osirix MD workstation (Apple Mac). All chest CT images, including presence or absence of pulmonary opacities, location, type of opacities, and extent, were independently examined by two primary interpreting radiologists, who were not aware of any clinical or laboratory findings or patient outcomes. A third senior radiologist resolved any disagreement between two primary interpreting radiologists with discussion. The lung lesions were categorized into 1) right lung left lung, or bilateral, and 2) peripheral predominant (defined as outer one-third of the lung), central predominant (defined as the inner two-third of the lung tissue), or diffuse. The number of lobes involved was recorded. The lung abnormalities were also classified into anterior and posterior locations. The lung tissue anterior to a line drawn midway on axial CT and the portion behind it was defined as anterior and posterior, respectively. According to the Fleischner Society Glossary [17] for thoracic imaging, Lung lesions were enumerated for each patient. A semi-quantitative CT score was used to quantify the extent of pulmonary abnormalities by visually enumerating the percentage of the total lung involvement.

### Statistical analysis

Discrete variables are expressed as frequencies, while continuous variables are expressed as mean ± SD. The agreement between two interpreting radiologists for CT findings was evaluated with the Kappa method. According to Landis and Koch, an inter-observer agreement was considered poor for a kappa value of 0.01-0.20, slight for 0.21-0.40, fair for 0.41-0.60, moderate for 0.61-0.80, and substantial for 0.81-1.0. There was almost a perfect agreement (Cohen's Kappa of 0.91) in reading CT images between the two primary radiologists. All analyses were performed using the Statistical Package for Social Sciences, version 15 (SPSS, Chicago, IL, USA).

## Results

### Sociodemographic factors

Three hundred and twelve patients with a mean age of 43.18 (± 8.27 years) were enrolled in the study. Most of the examined patients were males (65.4%). Of the 312 patients, 228 (73.1%) patients had a history of contact with RT-PCR confirmed COVID-19 or travel to a high-risk area within or outside the country. In our study population, males (65.4%) were predominately infected with COVID-19. Cough was the most frequent (48.1%) clinical presentation, followed by fever (47.1%). The mean WBC count was 6.53(±1.57), whereas increased lymphocyte and CRP count were found in 69 (22.1%) and 270 (86.5%) patients, respectively (Table 1).

**Table 1** Demographics, clinical characteristics, and laboratory data for COVID-19 infected patients (N =312)

Characteristics	N (%)
Mean age, years	43.18 ± 8.27
Male	204 (65.4)
History of contact with a COVID-19 patient or travel to a high-risk zone	228 (73.1)
Comorbidities	
Hypertension	51 (16.3)
Diabetes mellitus	24 (7.7)
Chronic liver disease	18 (5.8)
Rheumatoid arthritis	21 (6.7)
Clinical presentation	
Fever	147 (47.1)
Cough	150 (48.1)
Sore throat	51 (16.3)
Dyspnea	117 (37.5)
Malaise/Fatigue	117 (37.5)
Increased respiratory rate (> 30 /min)	51 (16.3)
Reduced oxygen saturation (< 90%)	57 (18.3)
Laboratory parameter	
Mean WBC count (normal value 4-11 × 10 <sup>9</sup> /L)	6.53 ± 1.57
Lymphocyte count (normal value 1.1-3× 10 <sup>9</sup> /L)	
Increased	69 (22.1)
Decreased	243 (77.9)
Increased CRP (normal value < 10 mg/L)	270 (86.5)

COVID-19, coronavirus disease; CRP: C- reactive protein; WBC, White blood cells, WBC: white blood cells

### Distribution of lung findings on chest CT

A perfect agreement (Cohen's Kappa of 0.91) was observed in reading CT images between the two primary interpreting radiologists. Regarding the distribution of lung findings on chest CT examination, lung parenchymal abnormalities were reported in 294 (94.2%) and normal chest CT in 18 (5.8%) COVID-19 patients. The laterality of lung involvement was recorded in 294 (94.2%) patients, and bilateral lung involvement (45.6%) was the commonest among the patients with abnormal CT findings. The involvement of multiple lobes was the most common in patients with lung parenchymal abnormalities. Of the 312 patients, 126 (42.9%) patients had involvement of five lobes. Concerning axial distribution, peripheral distribution was the most frequent axial location of opacity in 288 (92.3%) patients (Figure 1), whereas none of the patients showed purely central distribution. Likewise, posterior distribution was found in 252 (80.8%) patients in terms of anterior-posterior distribution (Table 2).

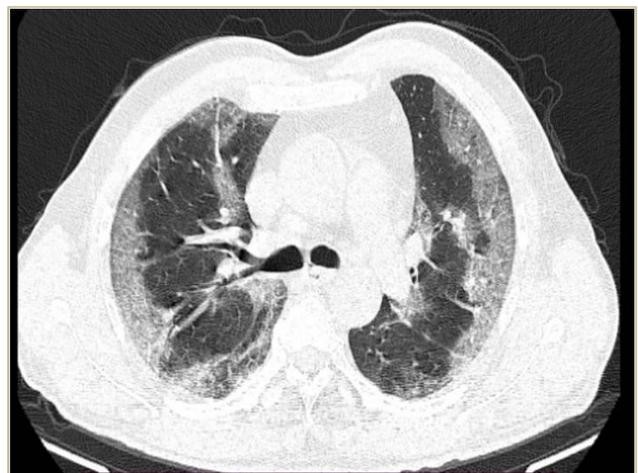

### The type of lung opacities

The type of lung opacities and additional findings on CT are summarized in Table 3. GGO was the dominant abnormality observed in 270(91.8%) patients. Pure GGO was seen in 108(36.7%) patients. GGO with interlobular septal thickening and intralobular lines producing crazy-paving pattern was reported in 117(39.8%) patients, while GGO mixed with consolidation was observed in 153(52.0%) patients (Figure 2, 3, and 4).

**Table 2** Distribution of lung findings on chest CT (n=312)

Lung parenchymal abnormalities on CT	N (%)
Normal CT	18/312(5.8)
Abnormal CT	294/312(94.2)
Laterality of lung involvement	
Bilateral	134/294(45.6)
Right lung	84/294(28.6)
Left lung	76/294(25.8)
Lobar involvement	
Right upper lobe	126/312(40.4)
Right middle lobe	72/312(23.1)
Right lower lobe	108/312(34.6)
Left upper lobe	132/312(42.3)
Left lower lobe	102/312(32.7)
Number of lobes involved	
Five lobes	126(42.9)
Four lobes	54(18.4)
Three lobes	46(15.6)
Two lobes	32(10.9)
One lobe	36(12.2)
Axial location of the opacity	
Central (inner 2/3rd of the lung)	0
Peripheral (outer 1/3rd of the lung)	288(92.3)
Central and Peripheral	207(66.3)
Antero-posterior location	
Anterior	0
Posterior	252(80.8)
Anterior and posterior	108(34.6)

CT: computed tomography

**Figure 1:** HRCT lung showing extensively peripheral subpleural involvement of lungs on both sides with thickening of interlobular interstitium within ground-glass opacity in both lungs

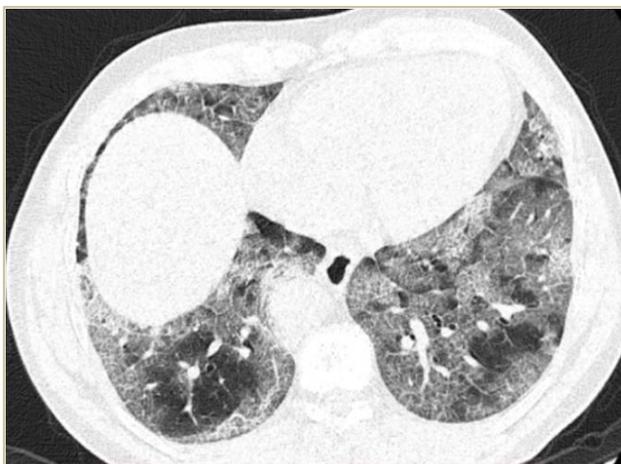

Reticulation was observed in 126 (42.9%) patients. A relatively smaller number of cases showed subpleural curvilinear lines in 45 (15.3%) patients (Figure 5), air bronchogram sign in 90(30.6%) patients (Figure 6), halo sign in 15 (3.1%) patients (Figure 7a), atoll or reverse halo sign in 45 (15.3%) patients (Figure 7b), perilesional /intralesional vessel enlargement in 192 (65.3%), and air bubble sign in 18 (6.1%) patients. Forty-five patients (15.3%) showed bronchial wall thickening,

whereas eighteen patients (6.1%) showed bronchodilatation. Vasculopathy was found in 45 (15.3%) patients (Figure 8). Spontaneous pneumomediastinum and spontaneous pneumothorax (Figure 9) was found in 18(6.1%) patients and 15(5.1%) patients, respectively. CT findings revealed that none of the patients showed pure consolidation, cavitation, pleural effusion, pericardial effusion, and mediastinal lymphadenopathy. A higher number [126 (42.9%)] of patients with sequelae of old healed tuberculosis were observed in CT findings of existing lung disease, followed by emphysema 18(6.1%) and fibrosis/interstitial lung disease 18(6.1%).

**Table 3** Type of lung opacities and additional findings on CT (N=312)

Lung opacities	N (%)
GGO	270(91.8)
Pure GGO	108(36.7)
GGO with crazy paving pattern	117(39.8)
Pure consolidation	0
Mixed pattern (GGO with consolidation)	153(52)
Sub pleural linear/curvilinear lines	45(15.3)
Nodules	15(5.1)
Reticulations	126(42.9)
Halo sign	15(5.1)
Reverse halo sign	45(15.3)
Cavitation	0
Perilesional /Intralesional vessel enlargement	192(65.3)
Bronchial wall thickening	45(15.3)
Bronchial dilatation	18(6.1)
Air bronchogram sign	90(30.6)
Air bubble sign	18(6.1)
<b>Additional findings</b>	
Pleural effusion	0
Pericardial effusion	0
Mediastinal lymphadenopathy	0
Vasculopathy	45(15.3)
Spontaneous pneumomediastinum	18(6.1)
Spontaneous pneumothorax	15(5.1)
<b>Findings of existing lung disease</b>	
Emphysema	18(6.1)
Sequelae of old healed tuberculosis	126(42.9)
Fibrosis/ Interstitial Lung Disease	18(6.1)

GGO: ground-glass opacities

**Figure 2:** Crazy paving appearance: Image showing ground-glass opacity with thickening of the interlobular interstitium.

## Discussion

Chest CT is a feasible modality to assess the severity of COVID-19 by evaluating lung pathology in COVID-19 patients [10]. The majority of the COVID-19 patients are asymptomatic during the early phase of the disease. CT scanning can identify the patients with minimal symptoms and those who were asymptomatic at admission. Positive chest CTs are found in asymptomatic patients, whereas, in contrast, negative chest CTs are found in symptomatic patients during the early phase of the disease [13, 15, 16]. In the present study, no lung parenchymal abnormalities were observed in the majority of the RT-PCR confirmed COVID-19 patients. Controversially, the higher percentage (66.3%) of negative CT in the present study refute from previous results who have found lung parenchymal abnormalities in 71.8% [17], 96.6% [18], 100% [19], 88.7% [20], 89.7% [21], 57.8% [22], and 65.3% [13] RT-PCR confirmed COVID-19 patients. The discrepancy of the low incidence of CT findings in the present study with the previous studies may be due to the following reasons: 1) a Low number of comorbidities was found in the population. 2) The study was performed in all consecutive symptomatic RT-PCR confirmed COVID-19 patients, irrespective of the severity of symptoms; and 3) There is a high proportion of young patients ( $43.18 \pm 8.27$  years) in our study. Pulmonary parenchymal abnormalities in crazy paving patterns and coalescing consolidations are associated with poor clinical outcomes. Pathologically, it may increase alveolar damage in the COVID-19 patients. The present study revealed the predominance of GGOs with posterior and peripheral predilection with a bilateral and multilobar distribution of pulmonary opacities among the patients with lung parenchymal abnormalities on chest CT. GGO was the dominant abnormality found in 45 (44%) patients, in which pure GGO (11.5%), GGO with superimposed crazy paving pattern (12.5%), or GGO admixed with consolidation (16.3%) were noted. The findings are consistent with the previous studies [22, 24]. The bilateral and mixed involvement of posterior and peripheral may be the lurking enemy behind the poor clinical outcomes in COVID-19 patients. The presence of vascular enlargement may be beneficial to differentiate COVID-19 pneumonia from non-COVID-19 pneumonia, as vascular enlargement arises due to the vasodilatory effect of proinflammatory cytokines, small vessel pulmonary embolism, and infection-induced pulmonary vasculitis [22, 25]. In concordance with the previous studies [17, 18, 22], our study also found the segmental or subsegmental intra-lesional or peri-lesional pulmonary vessel enlargement. Certain limitations of this study are worthy of mention. Firstly, it was a single-center study with small sample size, so this result should be cautiously used to extrapolate CT predictive values, which may differ based on the disease prevalence, different populations, and periods. Secondly, we emphasized examining initial or baseline CT findings without follow-up and did not conduct follow-up to check for temporal modifications (progression, stability, or dissipation) in pulmonary abnormalities. Lastly, valuable information such as the presence or absence of underlying respiratory or cardiac comorbidities (or both) in the study population were not examined; thus, GGO, interlobular septal thickening, and pleural effusion could be due to the presence of underlying cardiac disease. Future controlled studies that segregate the

direct pulmonary effects from the COVID-19 from those caused by the underlying medical diseases could prove beneficial for the future treatment of such patients.

### Limitation of study

Certain limitations of this study are worthy of mention. Firstly, it was a single-center study with small sample size, so this result should be cautiously used to extrapolate CT predictive values, which may differ based on the disease prevalence, different populations, and periods. Secondly, we emphasized examining initial or baseline CT findings without follow-up and did not conduct follow-up to check for temporal modifications (progression, stability, or dissipation) in pulmonary abnormalities. Lastly, valuable information such as the presence or absence of underlying respiratory or cardiac comorbidities (or both) in the study population were not examined; thus, GGO, interlobular septal thickening, and pleural effusion could be due to the presence of underlying cardiac disease. Future controlled studies that segregate the direct pulmonary effects from the COVID-19 from those caused by the underlying medical diseases could prove beneficial for the future treatment of such patients.

## Conclusion

This study can conclude that a higher incidence (94.2%) of abnormal chest CTs in mildly symptomatic RT-PCR confirmed COVID-19 patients. Of note, CT findings revealed the manifestation of GGOs in a bilateral and multilobar distribution with posterior and peripheral predilection in COVID-19 pneumonia patients. However, this finding should be confirmed by more extensive studies.
